

AI-Usage Transparency Note - Simple Grocery Store API QA Testing Project

Author: Denis Kondratyev

Course: TCQA46 Software QA & Automation, Technion

I used Claude (Anthropic) as a technical assistant on this project, under my own direction. Here's an honest breakdown of where it was and wasn't involved.

My own work (not AI-generated):

All 53 manual test cases across Products, Cart, Auth, and Orders were designed, executed, and evaluated by me directly against the live API. All four defects (results param accepting invalid values, available param accepting non-boolean values, clientName accepting digits-only input, customerName accepting an empty string on PATCH) were found through my own manual testing. Claude did not discover, suggest, or predict any of them.

Where I used AI assistance:

1. Postman data-driven automation, taught hands-on. This was my first time building CSV-driven test runs, so I asked Claude to walk me through the mechanics: the Iteration Data / Datafiles workflow in the Collection Runner, writing `pm.test()` assertions that branch on an expected-result column from the CSV, and using a Pre-request Script to conditionally omit a JSON body field (since Postman's `{{variable}}` substitution can't drop a key outright. I needed an "OMIT" sentinel pattern instead). I supplied the actual test data and expected outcomes myself, based on defects I had already found manually (TC-10-14, TC-33-38); Claude helped turn that into working scripts and debug runtime issues I hit along the way (a stale/unsaved request in the Runner, an email collision on repeated test runs).
2. Defect consolidation. I asked Claude to help me group defects I had already found individually (from TC-10, TC-18, TC-19, TC-38, TC-49) into a structured Defect Summary with a shared root-cause note, rather than reporting them as unrelated one-offs.
3. Document formatting. The final Test Case document and Defect Summary were laid out and styled (tables, structure) with Claude's help; the actual content (test steps, expected/actual results, defect descriptions) is mine.

What I did not use AI for: inventing test scenarios, deciding pass/fail outcomes, or generating results I hadn't actually observed. Every test case and defect in this submission reflects testing I performed myself against the live API; AI assistance was limited to technique, debugging, and formatting.
